Low Skew, Low Additive Jitter 3 x 5 LVPECL/LVDS/HCSL Fanout Buffer with one LVCMOS output

Features

- 3 to 1 input Multiplexer: Two inputs accept any differential (LVPECL, HCSL, LVDS, SSTL, CML, LVCMOS) or a single ended signal and the third input accepts a crystal or a single ended signal
- Five differential LVPECL/LVDS/HCSL outputs
- One LVCMOS output
- Ultra-low additive jitter: 24fs (integration band 12kHz to 20MHz at 625MHz clock frequency)
- Supports clock frequencies from 0 to 1.6GHz
- Supports 2.5V or 3.3V power supplies for LVPECL, LVDS or HCSL outputs
- Supports 1.5V, 1,8V, 2.5V or 3.3V power supplies for LVCMOS output
- Embedded Low Drop Out (LDO) Voltage regulator provides superior Power Supply Noise Rejection
- Maximum output to output skew of 40ps
- Device controlled via SPI

Functional Description

The ZL40235 is a programmable or hardware pin controlled low additive jitter, low power 3 x 5 LVPECL/HCSL/LVDS fanout buffer.

Two inputs can accept signal in differential (LVPECL, SSTL, LVDS, HSTL, CML) or single ended (LVPECL or LVCMOS) format and the third input can accept a single ended signal or it can be used to build a crystal oscillator by connecting an external crystal resonator between its XIN and XOUT pins. All the other components for building crystal oscillator are built in device such as load capacitance, series and shunt resistors.

The ZL40235 has five LVPECL/HCSL/LVDS outputs which can be powered from 3.3V or 2.5V supply. Each output can be independently enabled/disabled via SPI bus. The type of each output driver can be programmed to be LVPECL, HCSL or LVDS. Hence, the device can be configured to support application where different signal formats are needed.

The device operates from 2.5V+/-5% or 3.3V+/-5% supply. Its operation is guaranteed over the industrial temperature range -40°C to +85°C.

Clock Inputs

The following blocks diagram shows how to terminate different signals fed to the ZL40235 inputs.

Figure 3 shows how to terminate a single ended output such as LVCMOS. Ideally, resistors R1 and R2 should be 100Ω each and Ro + Rs should be 50Ω so that the transmission line is terminated at both ends with characteristic impedance. If the driving strength of the output driver is not sufficient to drive low impedance, the value of series resistor R_S should be increased. This will reduce the voltage swing at the input but this should be fine as long as the input voltage swing requirement is not violated (Table 8). The source resistors of Rs = 270Ω could be used for standard LVCMOS driver. This will provide 516mV of voltage swing for 3.3V LVCMOS driver with load current of (3.3V/2) *(1/(270Ω + 50Ω)) = 5.16mA.
For optimum performance both differential input pins (_p and _n) need to be DC biased to the same voltage. Hence, the ratio R1/R2 should be equal to the ratio R3/R4.

Clock Outputs

LVCMOS output OUT10 require only series termination resistor whose value is depending on LVCMOS output voltage as shown in Figure 11.

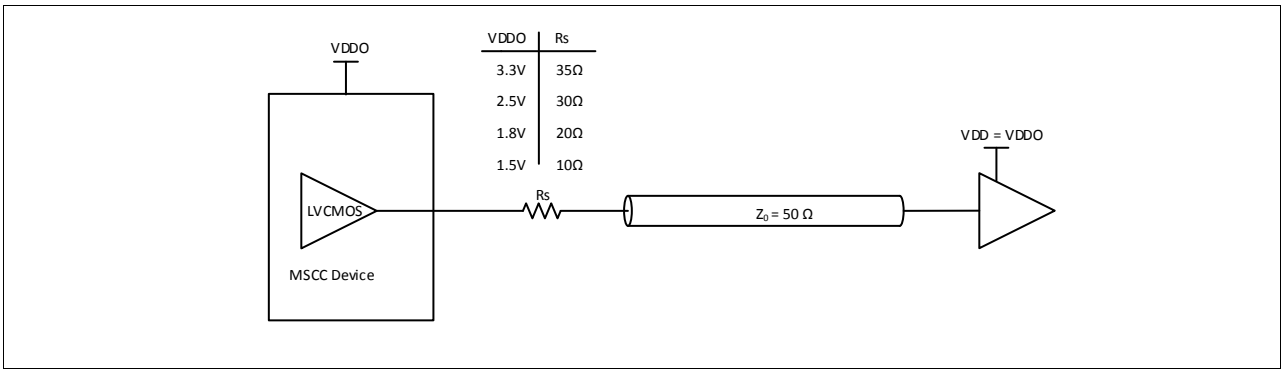

Figure 11. Termination for LVCMOS outputs

Differential outputs LVPECL and LVDS should have same termination as corresponding outputs described in previous section. HCSL outputs should be terminated with 33Ω series resistors at the source and 50Ω shunt resistors at the source or at the end on the transmission line. AC coupling and re-biasing is not required at the outputs when driving native HCSL receivers.

The device is designed to drive differential input of semiconductor devices. In applications that use a transformer to convert from the differential to the single ended output (for example driving an oscilloscope 50Ω input), a resistor larger than 10Ω should be added at the center tap of the primary winding to achieve optimum jitter performance as shown in Figure 12. This is to provide a nominal common mode impedance of 10Ω or higher which is typical for differential terminations.

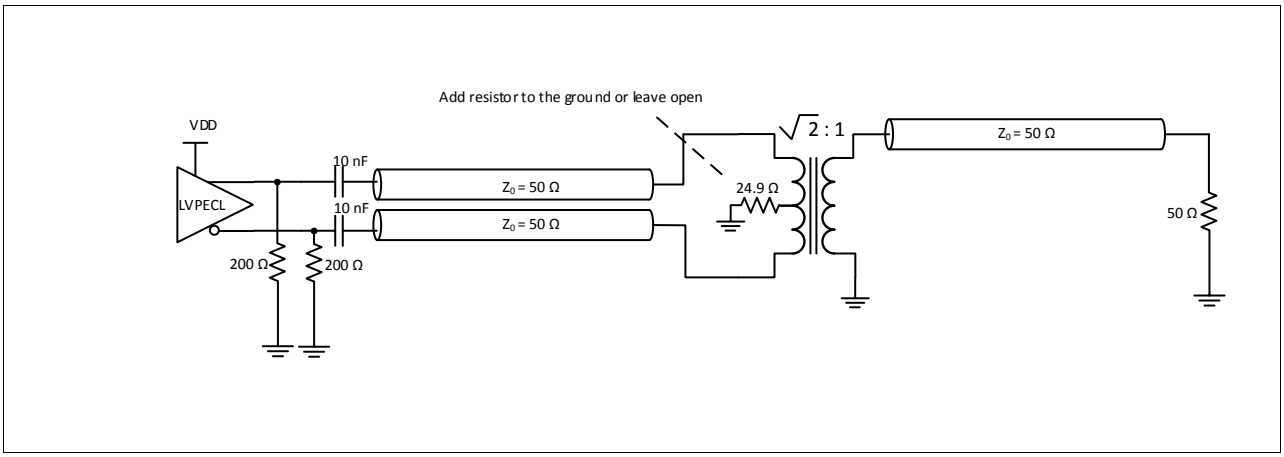

Figure 12. Driving a load via transformer

Crystal Oscillator Input

The crystal oscillator circuit can work with crystal resonators from 8MHz to 160MHz. As can be seen in the following figure only crystal resonator is required and all the other components are built-in the device. To be able support crystal resonators with different characteristics all internal components are programmable.

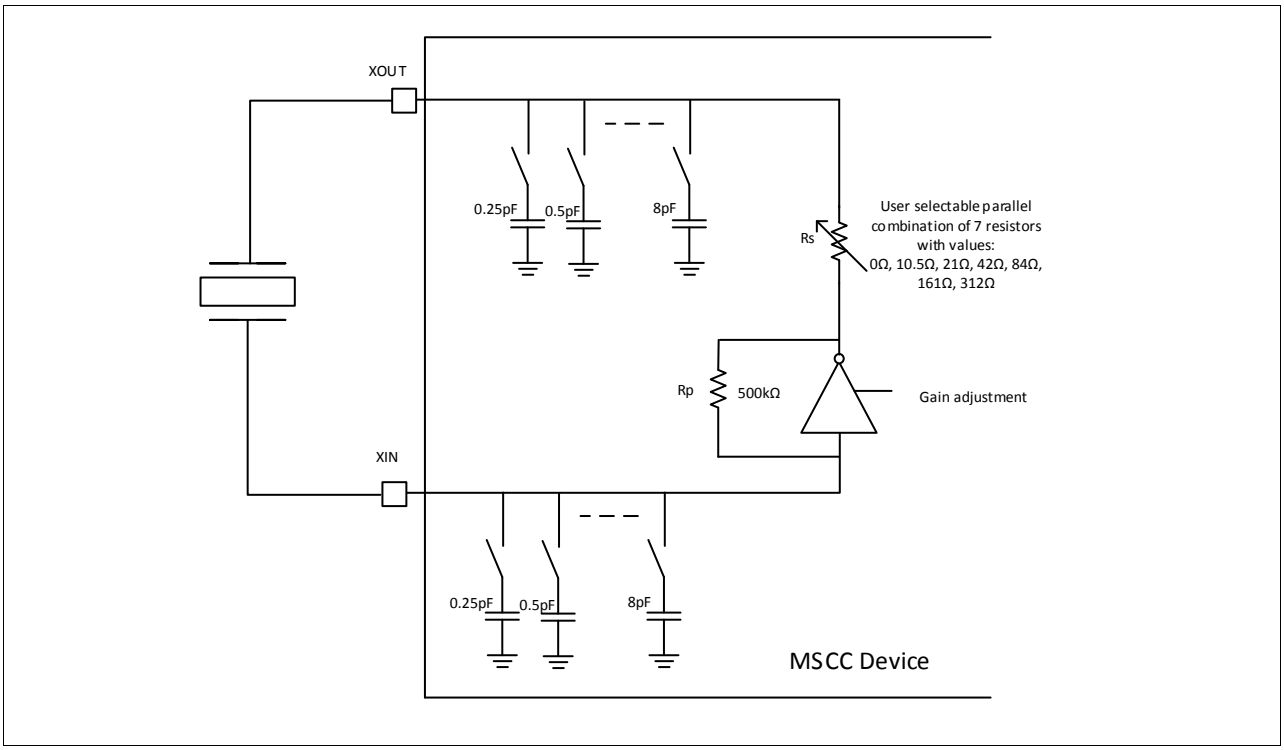

Figure 13. Crystal Oscillator Circuit

The load capacitors can be programmed from 0 to 21.75 pF (4pF default) with resolution of 0.25pF which not only meets load requirement for most crystal resonator but also allows for fine tuning of the crystal resonator frequency. The amplifier gain can be adjusted in five steps and series resistor can be adjusted as parallel combination of seven different resistors: 0Ω, 10.5Ω, 21Ω, 42Ω, 84Ω, 161Ω and 312Ω (84Ω default). Although the first resistor is 0Ω the series resistance Rs will be slightly higher than 0Ω due to parasitic resistance of the switch which connects resistor. Hence the minimum series resistance is achieved when all seven resistors are connected in parallel. The shunt resistor is fixed and its value is 500kΩ.

In Hardware Controlled mode the capacitive load is set at 4pF, internal series resistance to 84Ω and they cannot be changed. For Crystal requiring higher load or series resistance additional capacitance and/or series resistance can be added externally as shown in the Figure 14.

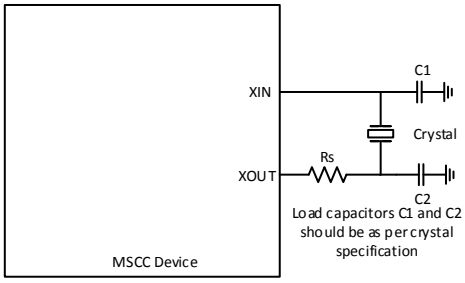

Figure 14. Crystal Oscillator Circuit in Hardware Controlled Mode

Termination of unused inputs and outputs

Unused inputs can be left unconnected or alternatively IN_0/1 can be pulled-down by 1kΩ resistor. Unused outputs should be left unconnected.

Power Consumption

The device total power consumption can be calculated as:

$$P_T = P_S + P_{XTAL} + P_C + P_{O\_DIF} + P_{O\_LVCMOS}$$

Where:

$P_S = V_{DD} \times I_S$ — The core power when XTAL is not used. The current is specified in Table 7. .If XTAL is running this power should be set to zero.

$P_{XTAL} = V_{DD} \times I_{DD\_XTAL}$ — The core power when XTAL is used. The current is provided in Table 7. If XTAL is not used this power should be set to zero.

$P_C = V_{DDO} \times I_{DD\_CM}$ — Common output power shared among all ten outputs. The current I_{DD_CM} is specified in Table 7.

$$P_{O\_DIF} = V_{DDO} \times (I_{DD\_LVDS} \times N_1 + I_{DD\_LVPECL} \times N_2 + I_{DD\_HCSL} \times N_3)$$

Output power where output currents are specified in Table 7.
N_1, N_2 and N_3 are number of enabled LVPECL, LVDS and HSCL outputs respectively and $N_1+N_2+N_3$ is less or equal to 5.

$$P_{O\_LVCMOS} = V_{DD\_LVCMOS} \times (I_{DD} \times f / 100MHz + V_{DD\_LVCMOS} \times C_{LOAD} \times f)$$

Dynamic LVCMOS output power. I_{DD} is specified in Table 7. If LVCMOS output is disabled this term is equal to zero.

Power dissipated inside the device can be calculated by subtracting power dissipated in termination/biasing resistors from the power consumption.

$$P_D = P_T - N_1 \times P_{LVPECL} - N_2 \times P_{LVDS} - N_3 \times P_{HCSL}$$

Where N_1, N_2 and N_3 are number of enabled LVPECL, LVDS and HSCL outputs respectively. Since there are five differential outputs $N_1 + N_2 + N_3$ is less or equal to 5.

$$P_{LVPECL} = (V_{OH} - V_B)^2 / 50\Omega + (V_{OL} - V_B)^2 / 50\Omega + (V_{OH} - V_B) \times V_B / 50\Omega + (V_{OL} - V_B) \times V_B / 50\Omega$$

V_{OH} and V_{OL} are the output high and low voltages respectively for LVPECL output
V_B is LVPECL bias voltage equal to V_{DD} – 2V

$P_{LVDS} = V_{SW}^2 / 100\Omega$ — V_{SW} is voltage swing of LVDS output.

$P_{HCSL} = (V_{SW} / 50\Omega)^2 \times (33\Omega + 50\Omega)$ — V_{SW} is voltage swing of HCSL output. 50Ω is termination resistance and 33Ω is series resistance of the HCSL output.

Power Supply Filtering

Each power pin (VDD and VDDO) should be decoupled with 0.1µF capacitor with minimum equivalent series resistance (ESR) and minimum series inductance (ESL). For example 0402 X5R Ceramic Capacitors with 6.3V minimum rating could be used. These capacitors should be placed as close as possible to the power pins. To reduce

the power noise from adjacent digital components on the board each power supply could be further insulated with low resistance ferrite bead with two capacitors. The ferrite bead will also insulate adjacent component from the noise generated from the device. Following figure shows recommended decoupling for each power pin.

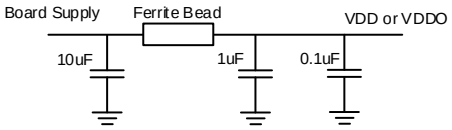

Figure 15. Power Supply Filtering

Power Supplies and Power-up Sequence

The device has four different power supplies: VDD, VDDO_A, VDDO_B and VDD_LVCMOS which are mutually independent. Voltages supported by each of these power supplies are specified in Table 1.

The device is not sensitive to the power-up sequence. For example commonly used sequence where higher voltage comes up before or at the same time as the lower voltages can be used (or any other sequence)

Host Interface

ZL30235 can be controlled via hardware pins (SEL pin tied low) or via SPI port (SEL pin tied high). The mode shall be selected during power up and it cannot be changed on the fly.

Hardware Control Mode

In this mode, ZL40235 is controlled via Input Select (IN_SEL0/1) pins which select which one of three inputs is fed to the output and show in Table 2 and OUT_TYPE_SEL0/1 pins which select signal level (LVPECL, LVDS, HCSL or Hi-Z) as shown in Table 3.
All input control pins have low input threshold voltage so they can be driven from the device with low output voltage (FPGA/CPLD). Supported voltages are between 1.2V and VDD (2.5V or 3.3V).

Table 2 Input clock selection

IN_SEL1	IN_SEL0	Selected Input
0	0	IN0_p, IN0_n
0	1	IN1_p, IN1_n

Table 3 Output Type Selection

OUT_TYPE_SEL1	OUT_TYPE_SEL0	Output
0	0	LVPECL
1	1	LVDS
1	0	HCSL
1	1	High-Z (Output Disabled)

Output is disabled synchronously on the falling edge of the input (t_2) as shown in Figure 16.

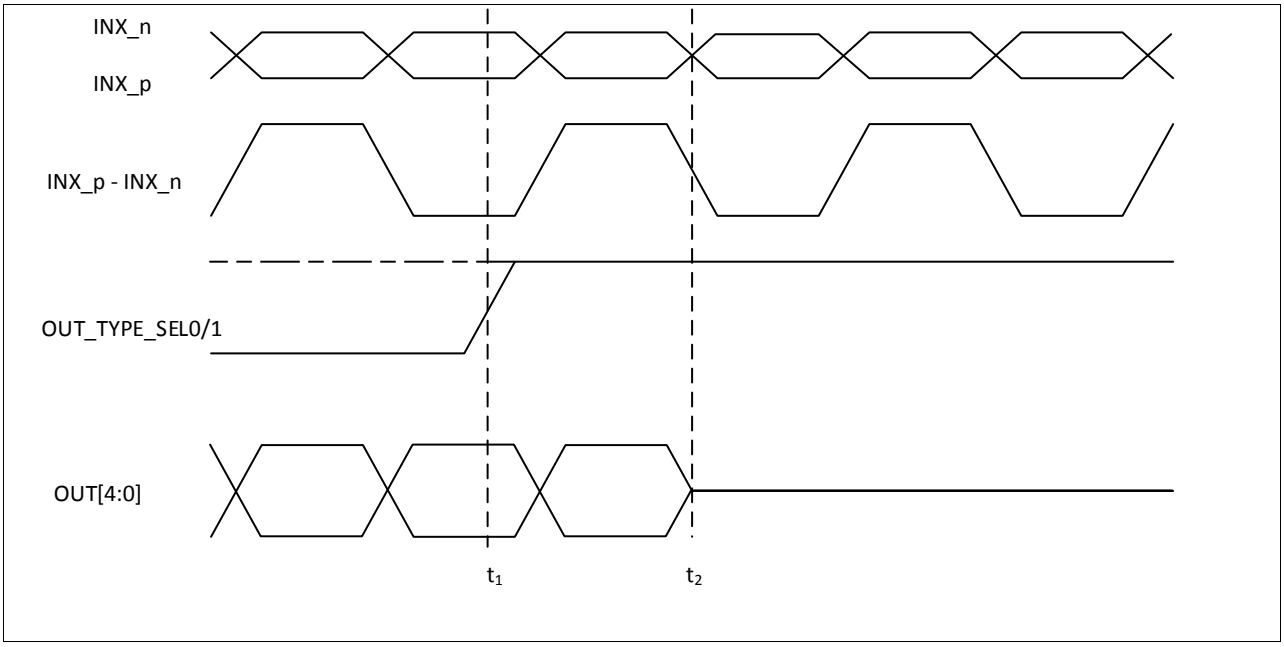

Figure 16. Output Disable

Outputs can be enabled by toggling one or both OUT_TYPE_SEL0/1 pins low depending on which type of interface needs to be enabled. As soon as one or both OUT_TYPE_SEL0/1 pins go low (t_1) the outputs will go from high-Z to low (OUTX_p = low, OUTx_n = high) and will start to track the input after the first falling edge (t_2) of the input signal as shown in Figure 17.

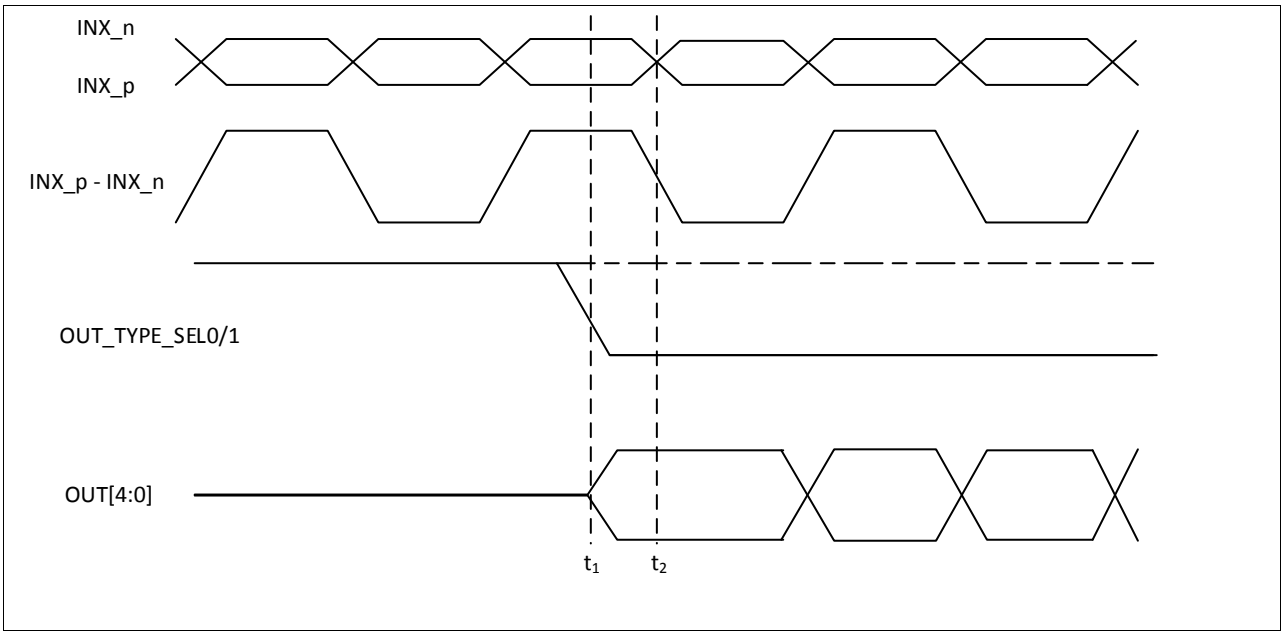

Figure 17. Output Enable

SPI Control Mode

ZL40235 is controlled via four pin SPI slave interface as shown in the following figure.

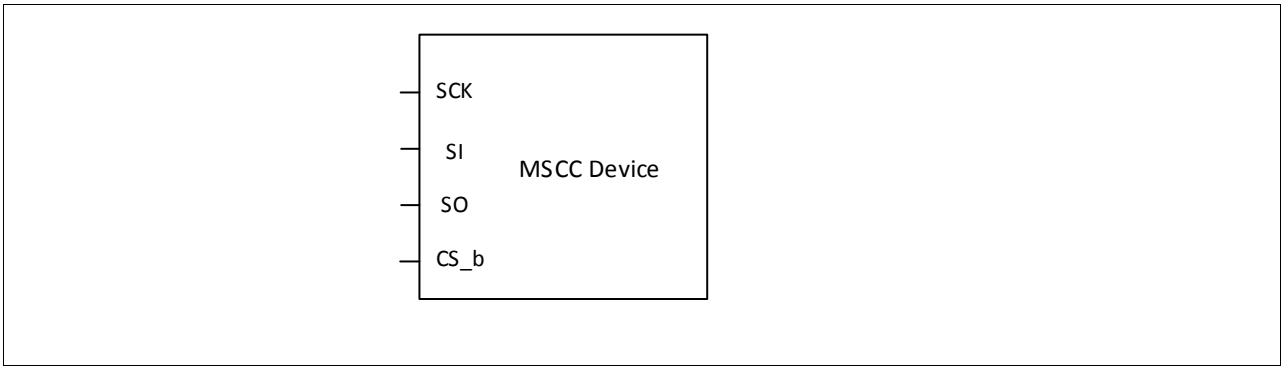

Figure 18. SPI slave interface

All SPI input pins have low threshold voltage so they can be driven from low output voltage SPI master device. Supported voltages are between 1.2V and VDD (2.5V or 3.3V). This allows device to be controlled from an FPGA with low voltage I/O supply.

The serial peripheral interface supports half-duplex processor mode which means that during a write cycle to the device, output data from the **SO** pin must be ignored. Similarly, the input data on the **SI** pin is ignored by the device during a read cycle.

The SPI interface supports two modes of access: Most Significant bit (MSb) first transmission or Least Significant bit (LSb) first transmission. The mode is automatically selected based on the state of **SCK** pin when the **CS_b** pin is active. If the **SCK** pin is low during **CS_b** activation, then MSb first timing is selected. If the **SCK** pin is high during **CS_b** activation, then LSb first timing is assumed.

The SPI port expects 1-bit to differentiate between read and write operation followed by 7-bit addressing and 8-bit data transmission. During SPI access, the **CS_b** pin must be held low until the operation is complete. Burst read/write mode is also supported by leaving the chip select signal **CS_b** is low after a read or a write. The address will be automatically incremented after each data byte is read or written.

Functional waveforms for the LSb and MSb first mode, and burst mode are shown in Figure 19 and Figure 20 respectively. Figure 21 shows an example of burst mode operation which allows user to read or write consecutive location in the register map.

Table 33 6x6mm QFN Package Thermal Properties

Parameter	Symbol	Condition	Value	Units
Maximum Ambient Temperature	T_A		85	°C
Maximum Junction Temperature	T_{JMAX}		125	°C
Junction to Ambient Thermal Resistance(1) (Note 1)	θ_{JA}	still air	22.2	°C/W
		1m/s airflow	17.6	
		2.5m/s airflow	15.8	
Junction to Board Thermal Resistance	θ_{JB}		7.2	°C/W
Junction to Case Thermal Resistance	θ_{JC}		14.3	°C/W
Junction to Pad Thermal Resistance(2)	θ_{JP}	Still air	3.9	°C/W
Junction to Top-Center Thermal Characterization Parameter	Ψ_{JT}	Still air	0.2	°C/W

(1) Theta-JA (θ_{JA}) is the thermal resistance from junction to ambient when the package is mounted on an 4-layer JEDEC standard test board and dissipating maximum power

(2) Theta-JP (θ_{JP}) is the thermal resistance from junction to the center exposed pad on the bottom of the package)

Change History

June 2017 was the first release of the document.

July 2017 release changes:

- Modified power calculation in the Power Consumption section.

August 2017 release changes:

- Modified “Input driven by HCSL output” figure.
- Modified additive jitter for 156.25MHz input clock.
- Added Figure 44 and Figure 45.

Microsemi Corporation (Nasdaq: MSCC) offers a comprehensive portfolio of semiconductor and system solutions for aerospace & defense, communications, data center and industrial markets. Products include high-performance and radiation-hardened analog mixed-signal integrated circuits, FPGAs, SoCs and ASICs; power management products; timing and synchronization devices and precise time solutions, setting the world's standard for time; voice processing devices; RF solutions; discrete components; enterprise storage and communication solutions, security technologies and scalable anti-tamper products; Ethernet solutions; Power-over-Ethernet ICs and midspans; as well as custom design capabilities and services. Microsemi is headquartered in Aliso Viejo, California, and has approximately 4,800 employees globally. Learn more at www.microsemi.com.
